

# Exploring High-Energy Atmospheric Muons with IceCube: Investigating Prompt Muon Normalization and Unfolding the Muon Flux

Pascal Gutjahr

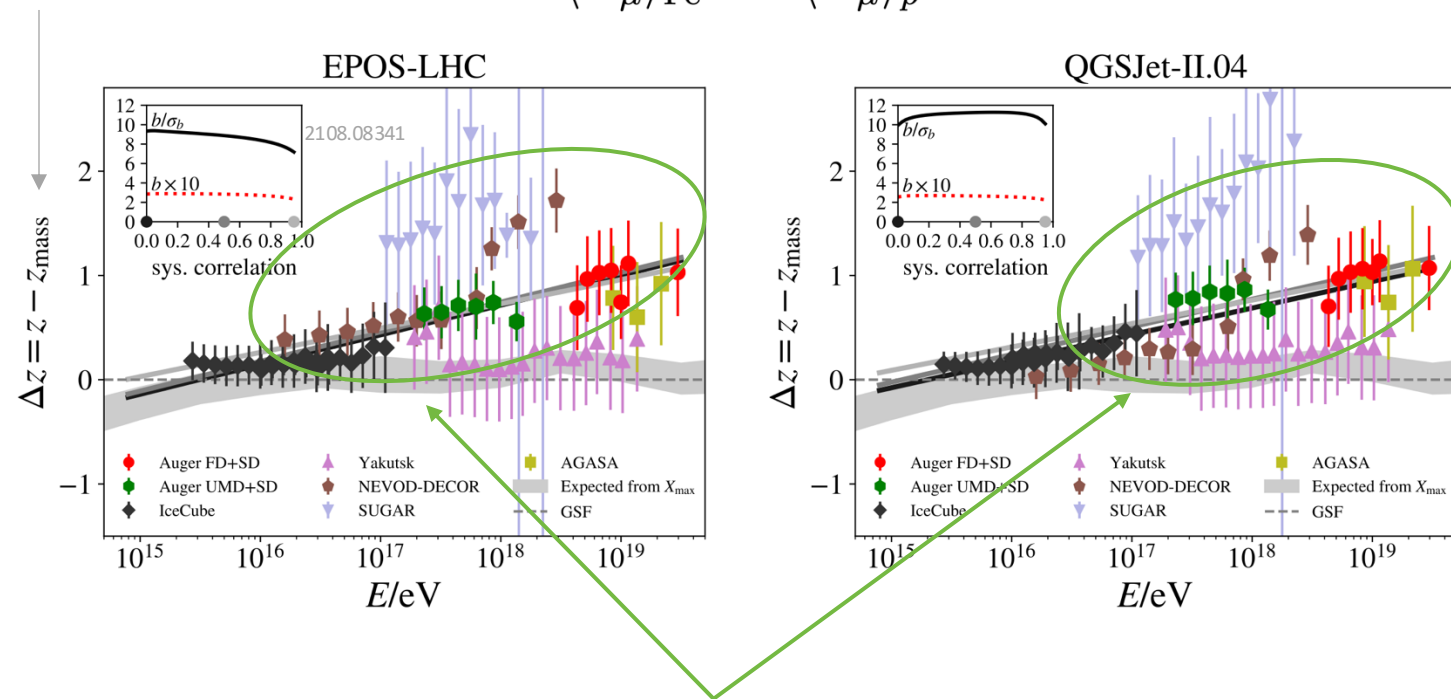

March 18, 2025

# Muon Puzzle & Hadronic Uncertainties

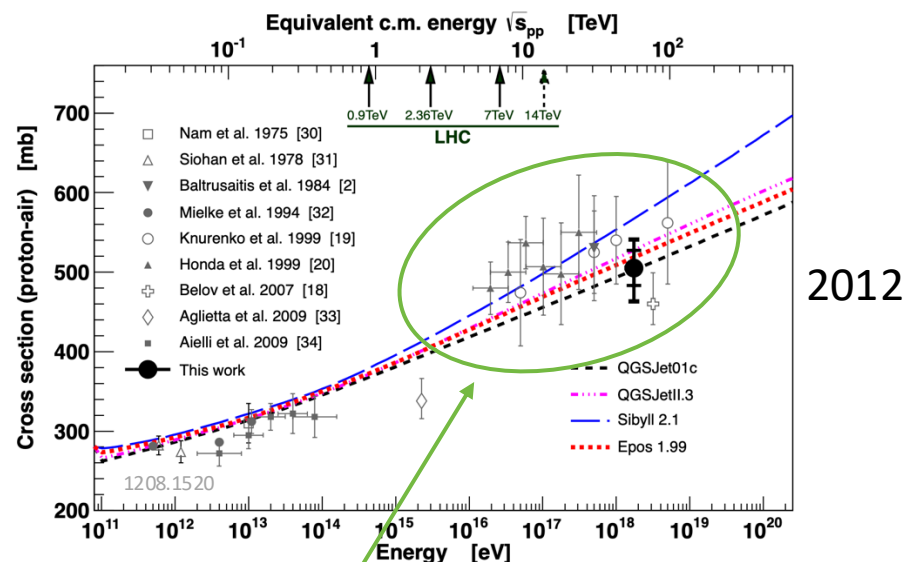

Expected  $z$  ("muon number")

"muon number"

$$z = \frac{\ln \langle N_\mu \rangle - \ln \langle N_\mu \rangle_p}{\ln \langle N_\mu \rangle_{\text{Fe}} - \ln \langle N_\mu \rangle_p}$$

- More muons measured than simulated for  $E > 40 \text{ PeV} \sim \text{cms } 8 \text{ TeV}$
- Precise pion/kaon ratio measurement needed

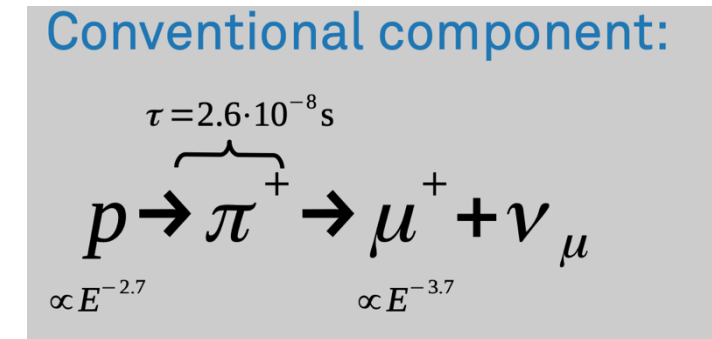

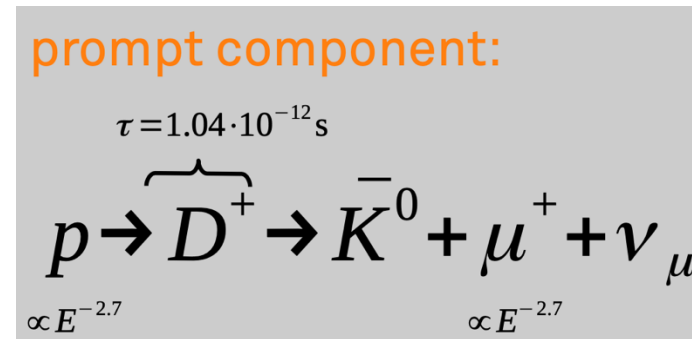

➤ Uncertainties at  $E > 10 \text{ PeV}$

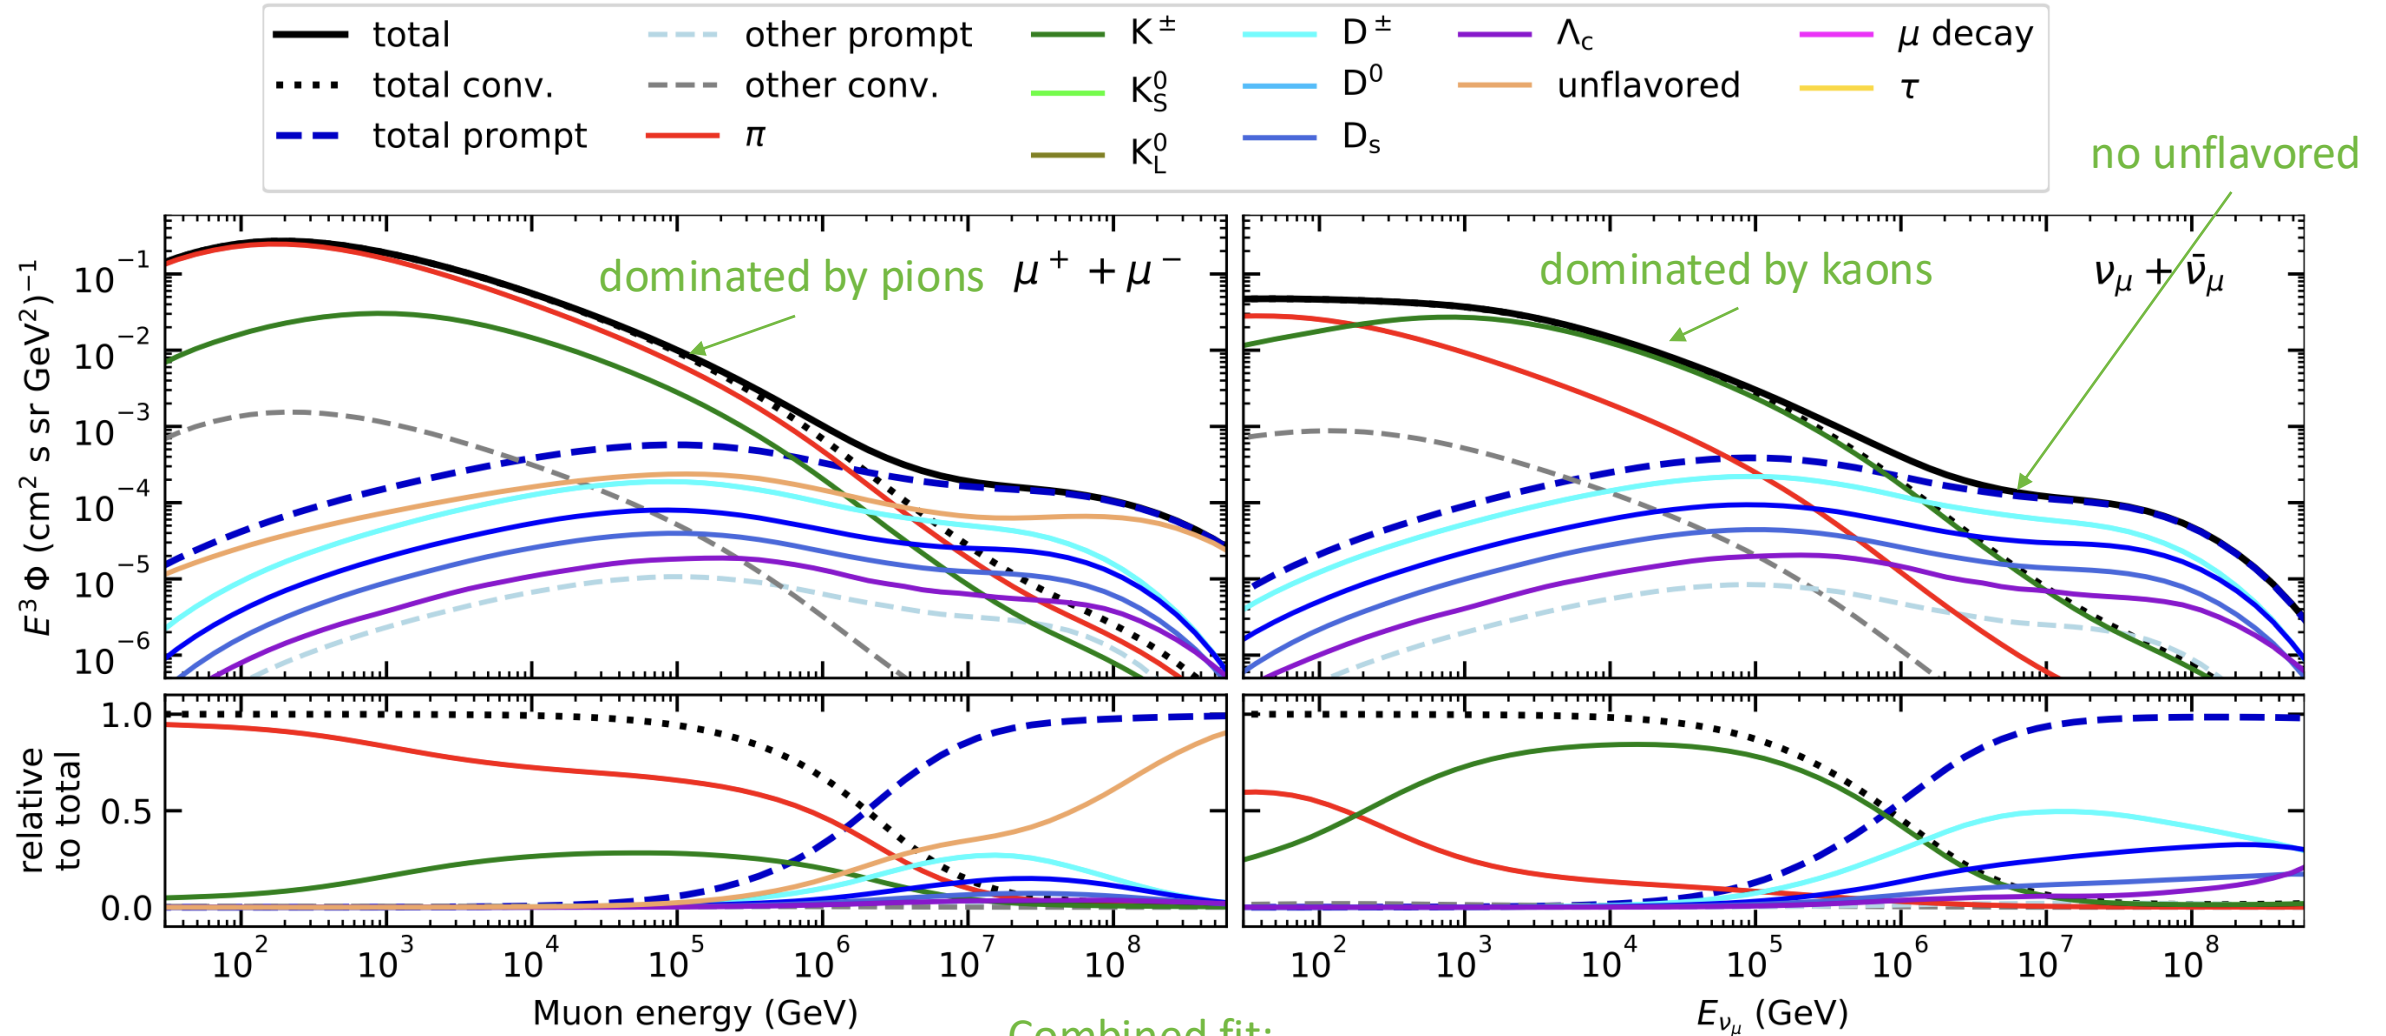

# Muon Flux

$$\Phi_{\text{tot}} = \Phi_{\text{prompt}} + \Phi_{\text{conventional}}$$

# Prompt Atmospheric Muons & Neutrinos

10.1103/PhysRevD.100.103018

Combined fit:

- handle on pion/kaon ratio
- handle on charmed mesons

## Analysis Goals

- 1) Measure prompt component of the atmospheric muon flux
- 2) Unfold a muon energy spectrum

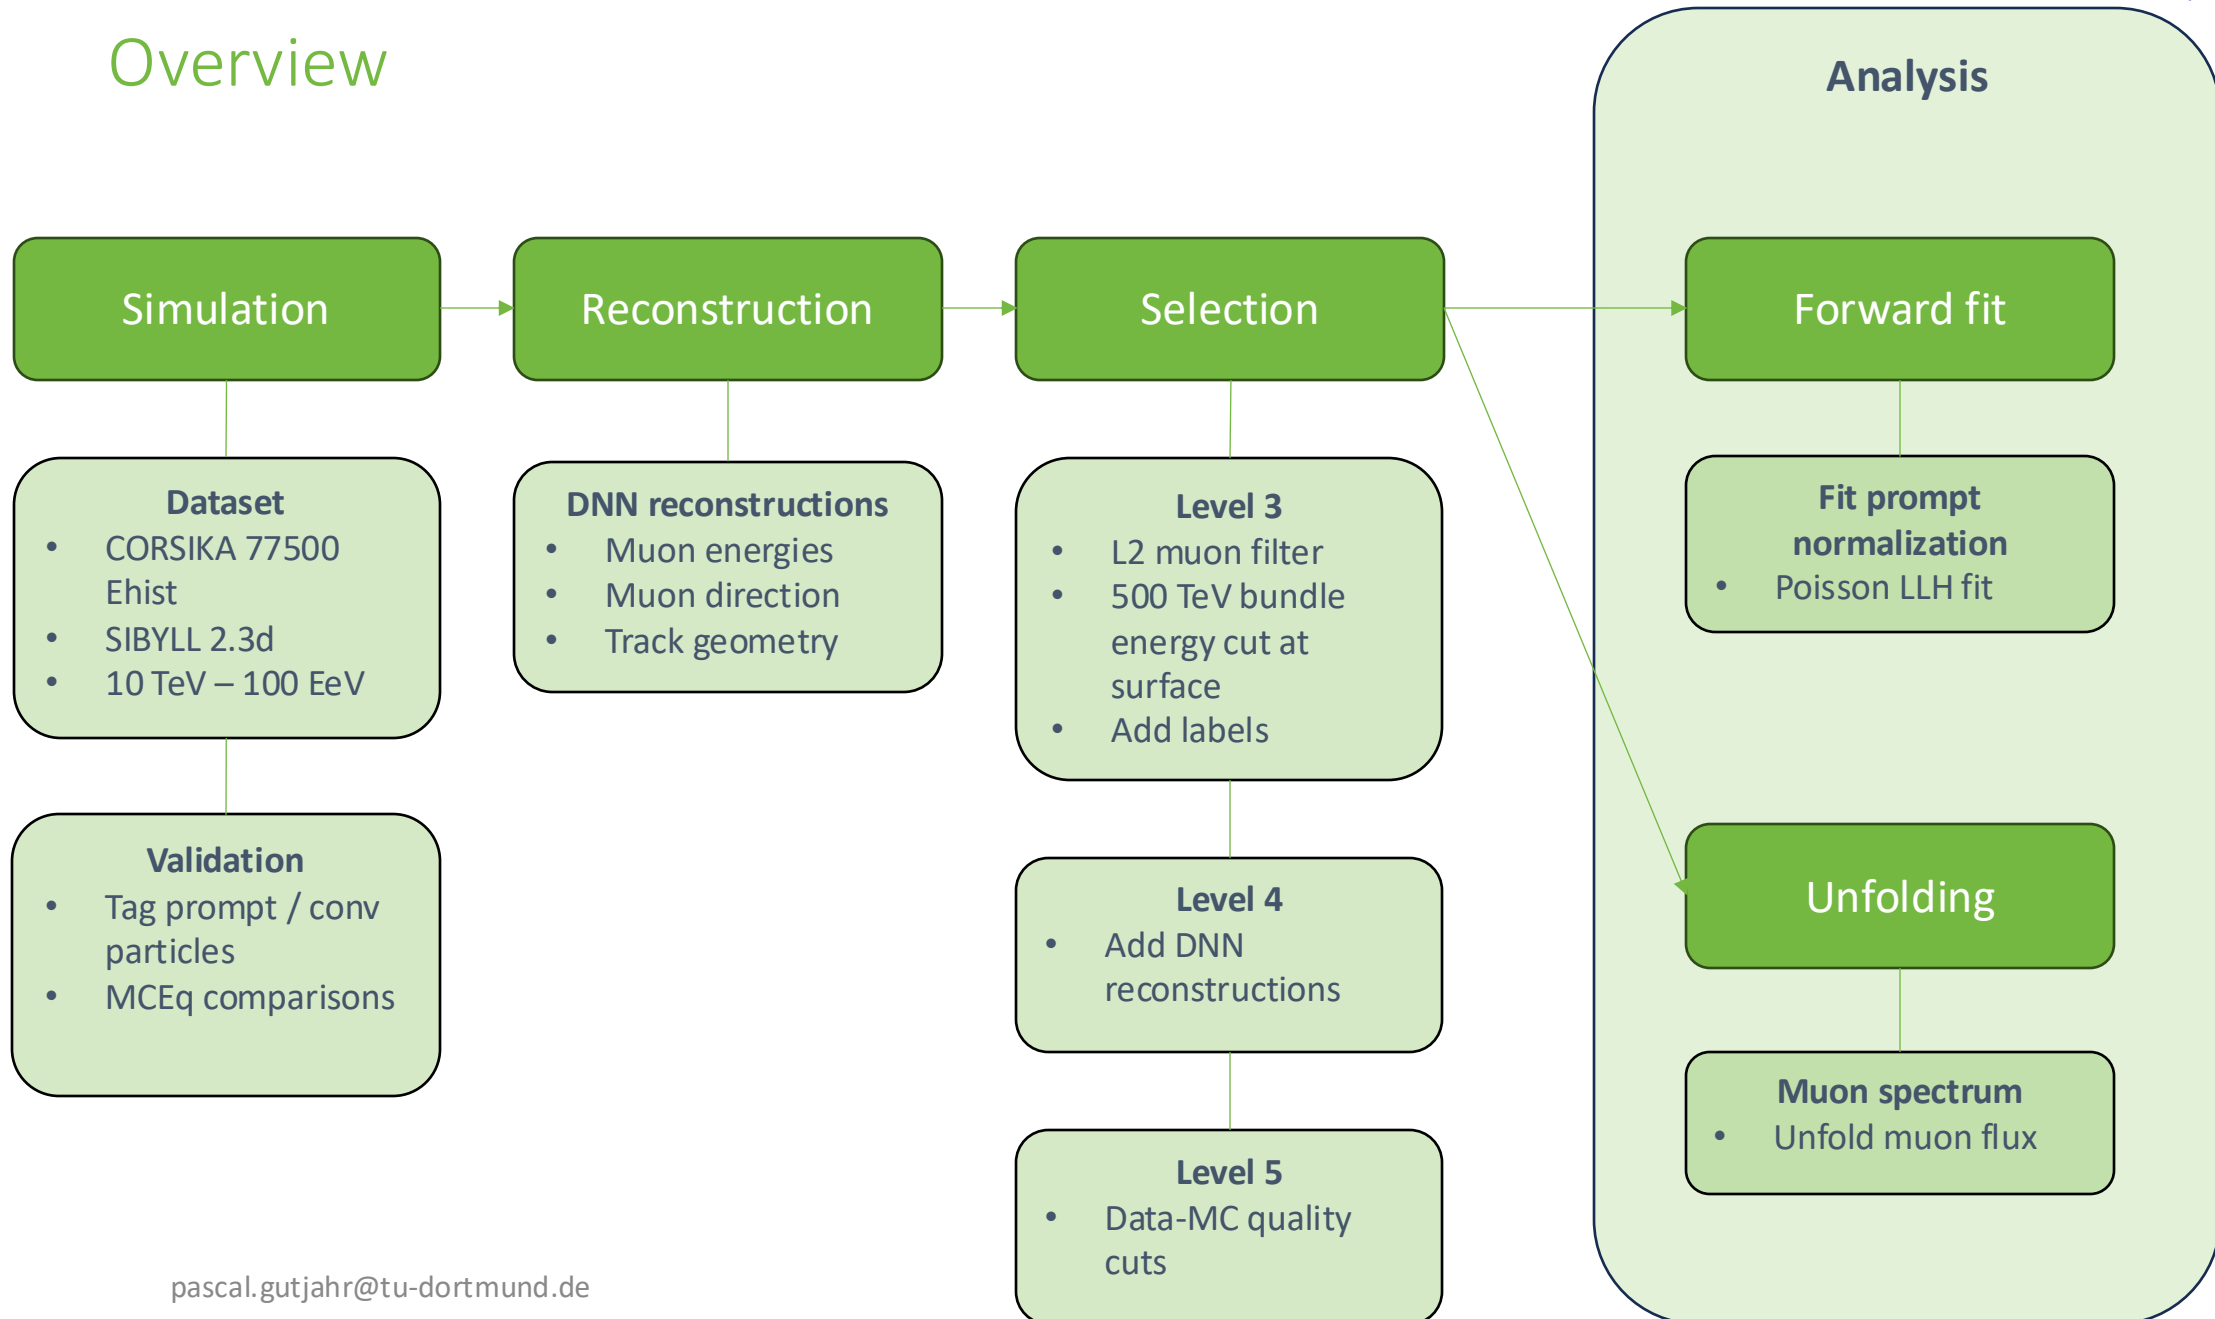

### Idea:

- New CORSIKA simulations with extended history
- Tag muons by parent → prompt or conventional
- Scale amount of prompt particles
  - Scaling saves time and resources instead of doing multiple simulations with different interaction models
  - Perform forward fit of the prompt normalization

### Future:

- Measure prompt neutrinos
- Combined muon and neutrino fit → pion/kaon ratio

# Overview

# Simulation

## CORSIKA 7 vs. MCEq

MCEq: tool to numerically solve the cascade equations that describes the evolution of particle densities as they propagate through a gaseous, dense medium

<https://github.com/mceq-project/MCEq>

➤ Good agreement for inclusive flux

Python package developed – PANAMA

- Execute CORSIKA 7 (multi core)
- Read DAT files → pandas DataFrames
- Parse EHIST option
- Calculate primary weightings

<https://github.com/The-Ludwig/PANAMA>

<https://arxiv.org/pdf/2502.10951>

# Forward Fit

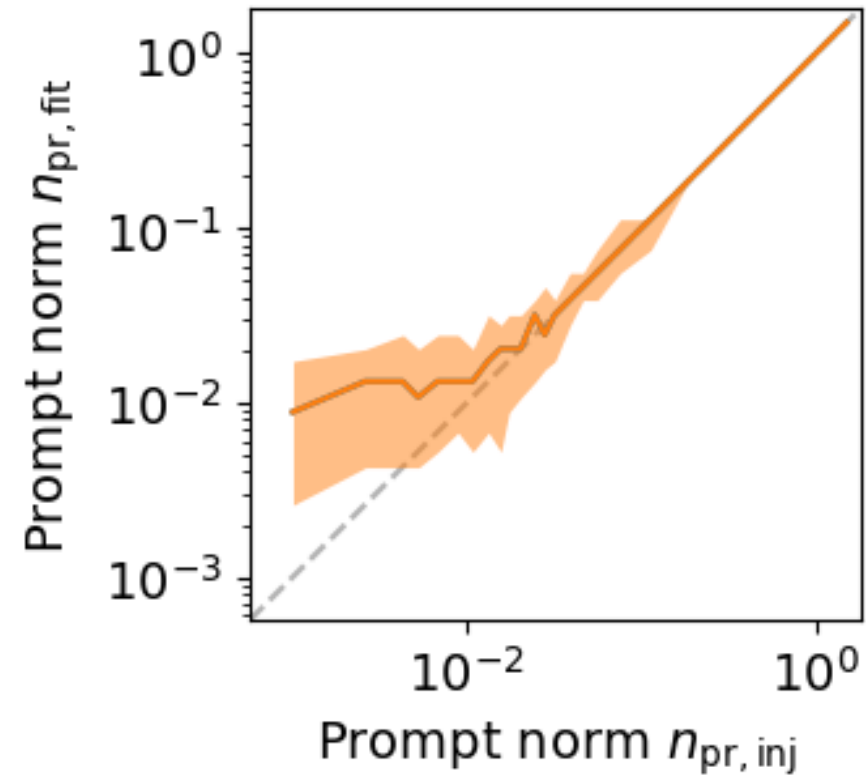

# Poisson Likelihood Fit

➤ Tagging allows scaling of prompt by factor  $n_{pr}$

$$C_1^{MC} = n_{pr} C_1^{MC,pr} + n_{conv} C_1^{MC,conv}, \dots, C_M^{MC} = n_{pr} C_M^{MC,pr} + n_{conv} C_M^{MC,conv}$$

$$p(C_i) = p_{\text{poisson}}(C_i; \lambda(n_{pr}) = C_i^{MC}(n_{pr})) = \frac{\lambda(n_{pr})^{C_i} e^{-\lambda(n_{pr})}}{C_i!}$$

➤ Bias starts at a prompt normalization of 0.1

# Discovery Potential and Sensitivity

Expectation for 1 year:

- 5 sigma discovery potential:  $0.102 \pm 0.005$
- Sensitivity:  $0.024 \pm 0.001$

Expectation for 10 years:

- 5 sigma discovery potential:  $0.032 \pm 0.001$
- Sensitivity:  $0.007 \pm 0.000$

## Caution:

- Limited MC statistics -> events are oversampled in pseudo dataset
- No systematics

# Unfolding

# Unfolding in a Nutshell

measured proxy  $g(y)$  =  $\int_{E_0}^{E_1} A(E_\mu, y) f(E_\mu) dE_\mu + b(y)$

detector response  $A(E_\mu, y)$

background  $b(y)$

true energy distribution  $f(E_\mu)$

Credit: T. Hoinka

1. discretized form:  $\vec{g} = A\vec{f} \leftrightarrow \vec{f} = A^{-1}\vec{g}$

2. maximum likelihood method:

$$\mathcal{L}(\vec{g}|\vec{f}) = \prod_{j=1}^M \frac{\lambda_j^{g_j}}{g_j!} \exp(-\lambda_j)$$

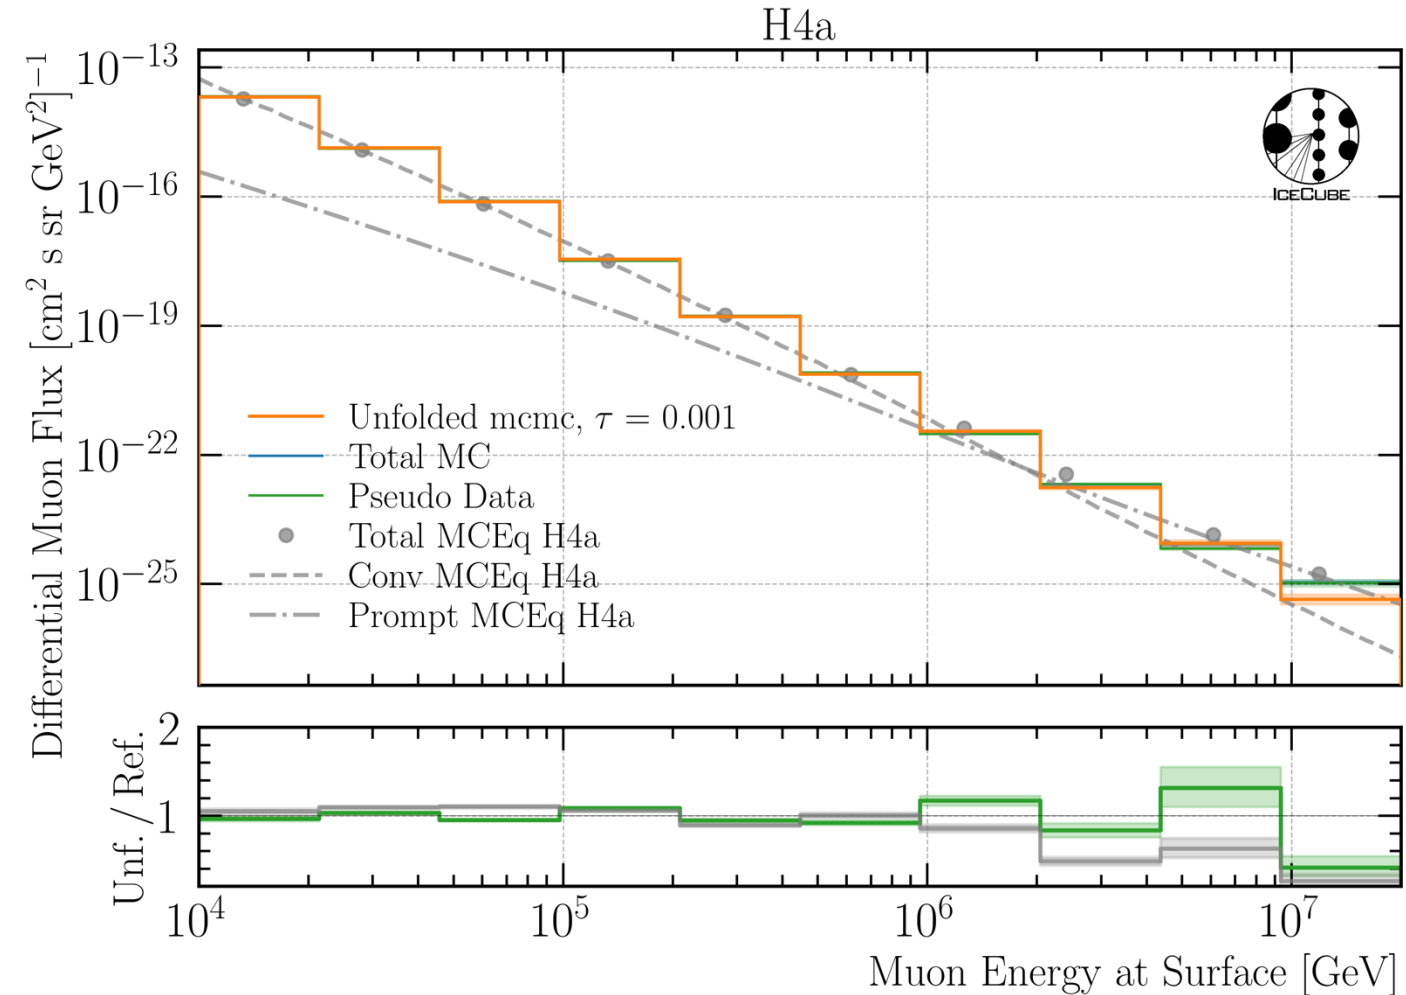

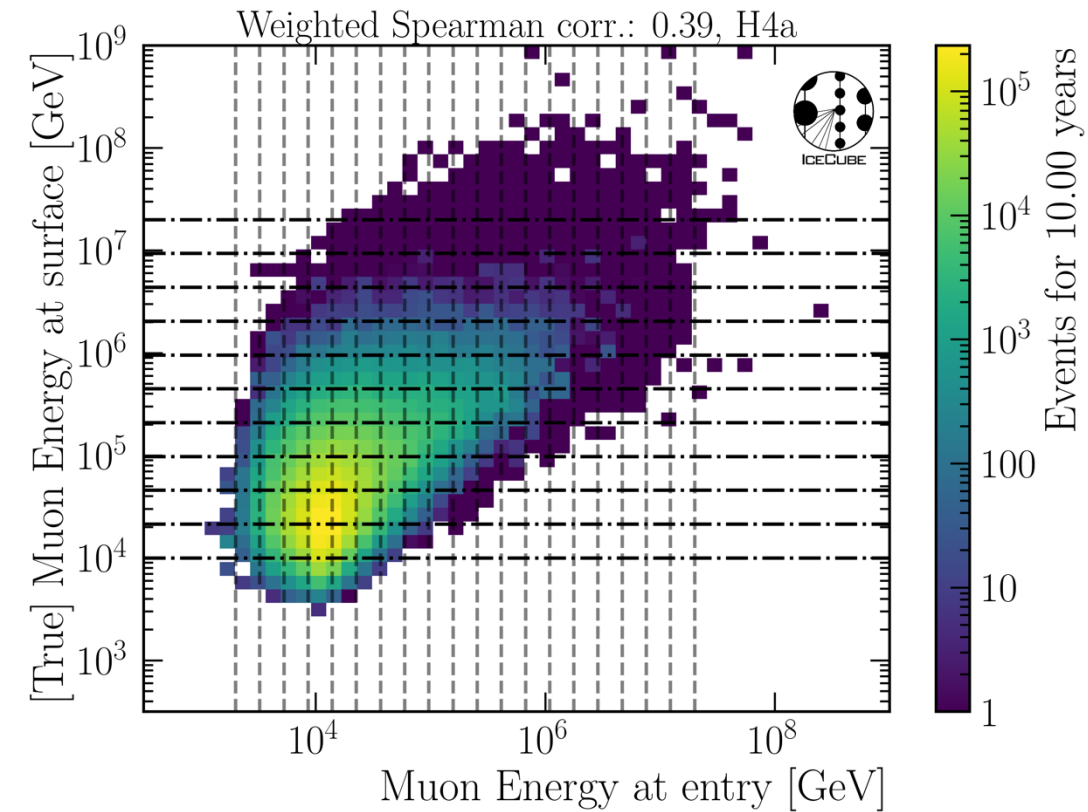

$$= \prod_{j=1}^M \frac{(A\vec{f})_j^{g_j}}{g_j!} \exp(-(A\vec{f})_j)$$

3. Thikonov regularization:

$$t(\vec{f}) = -\frac{1}{2} (C\vec{f})^T (\tau 1)^{-1} (C\vec{f})$$

4. maximize  $\log(\mathcal{L}(\vec{g}|\vec{f})) + t(\vec{f})$   
with respect to  $\vec{f}$  using  
Markov Chain Monte Carlo (MCMC)  
or Minuit

# Unfolded Muon Flux at Surface

## Conclusion & Outlook

- New CORSIKA simulations with parent information
  - Tag prompt and conventional muons
  - Validation: agreement with MCEq
  - arXiv: 2502.10951
  - [github.com/The-Ludwig/PANAMA](https://github.com/The-Ludwig/PANAMA)
- Fit of prompt normalization is promising
  - Include systematics
- Unfolding of muon flux at surface works
  - Fine-tune regularization strength

# Backup

# Possible Solutions

R. Ulrich, R. Engel, M. Unger, PRD 83 (2011) 054026

S. Baur, HD, M. Perlin, T. Pierog, R. Ulrich, K. Werner, arXiv:1902.09265

$$R = \frac{E_{\pi^0}}{E_{\text{other hadrons}}}$$

- Only changes to  $R$  can solve muon puzzle
- Small changes have large effect,  $R$  needs to be known to about 5 %

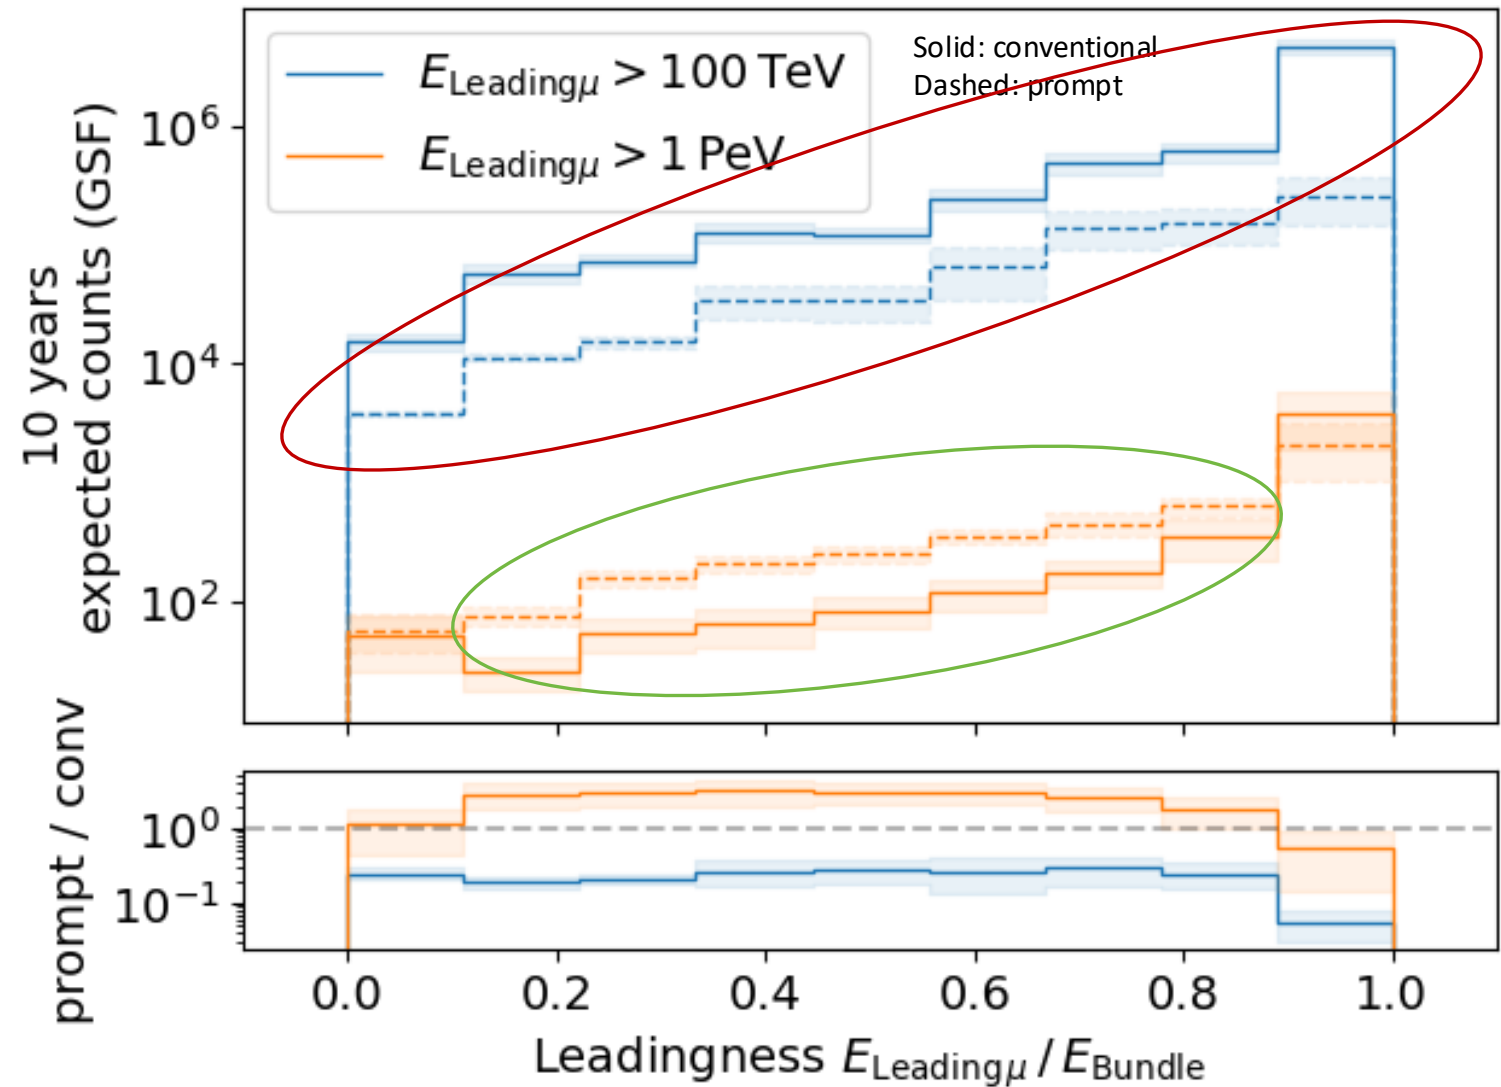

# Expected Muons For 10 Years: Leading vs. Bundle Energy (GSF)

- Both leading and bundle energy are sensitive to detect prompt
- Leading muon energy is more sensitive

# Leading Muon Energy Fraction

- Prompt dominates for energies  $> 1$  PeV
- Leading energy sweet spot: 0.1 – 0.9

# Leading Muon Contribution

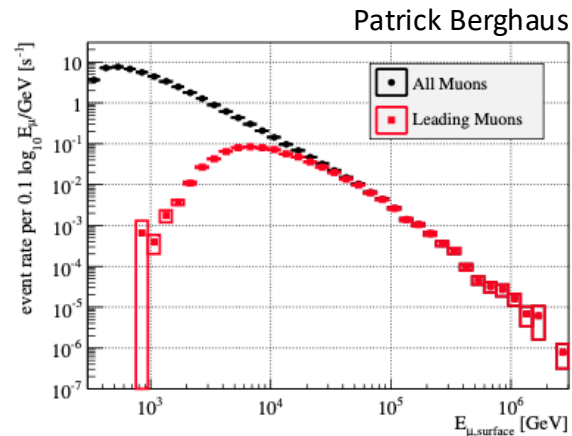

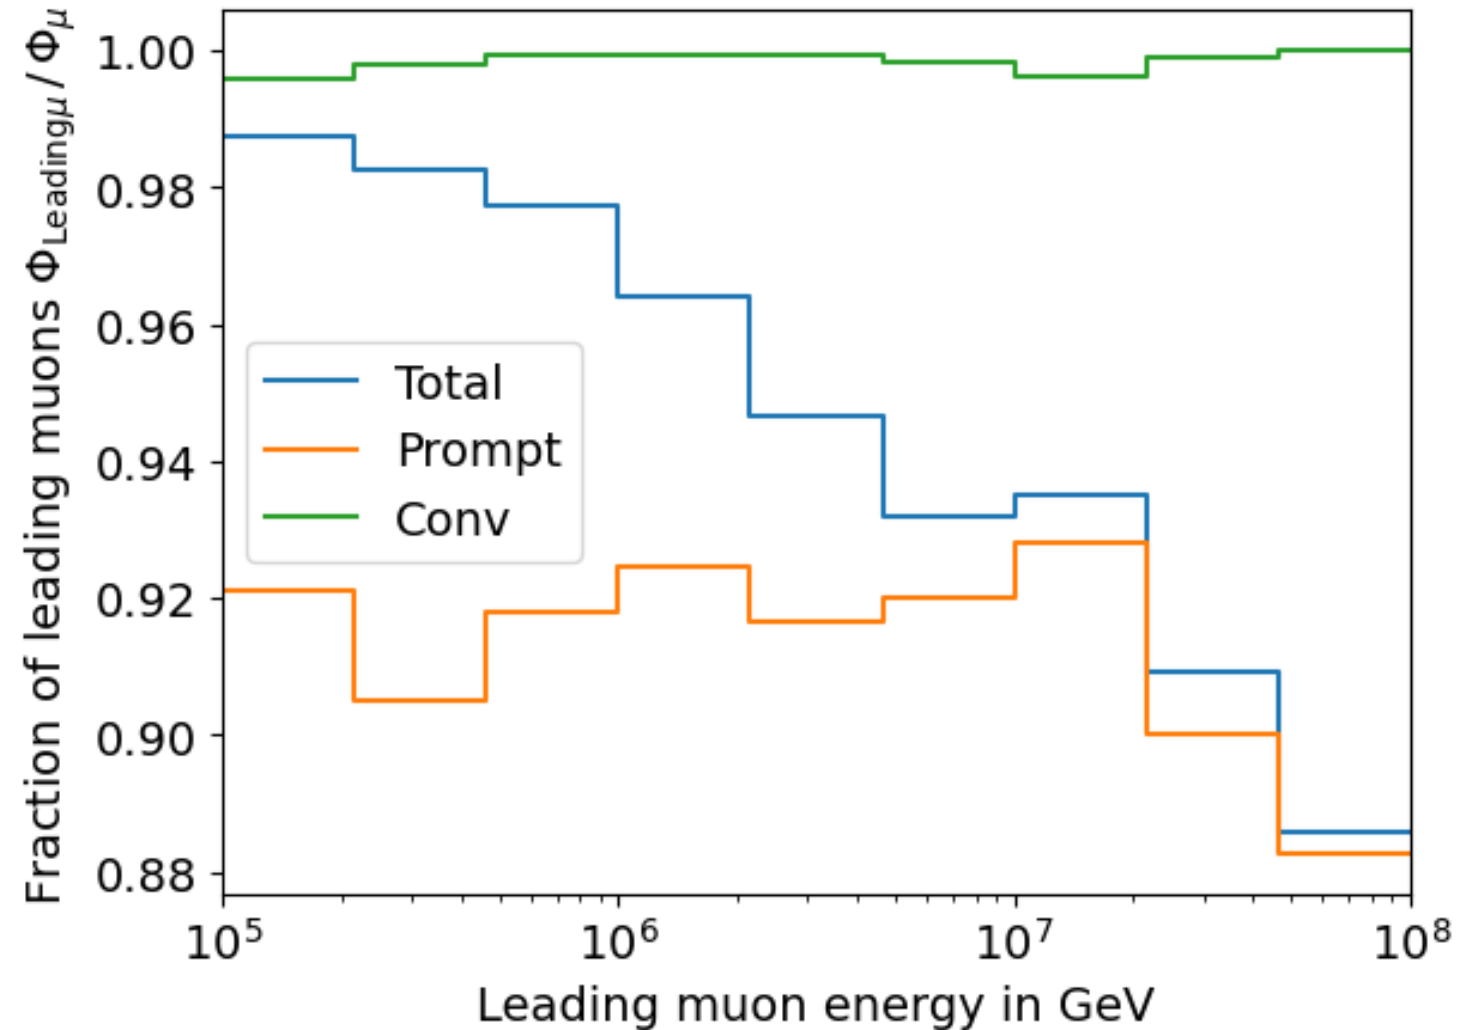

Figure 10: Surface energy distribution for all and most energetic (“leading”) muons in simulated events with a total of more than 1,000 registered photo-electrons in IceCube.

- Muons with energies between 100 TeV and 50 PeV dominate the bundle by more than 90%
- In average conventional muons are more dominant than prompt
- But: at high energies, there are more prompt than conventional events

➤ High leading energy fraction does not lead to more sensitivity to detect prompt

# Poisson Likelihood Fit

Prompt scaling/normalization

MC counts per bin  $i$

Conv norm = 1

$$C_1^{\text{MC}} = n_{\text{pr}} C_1^{\text{MC,pr}} + n_{\text{conv}} C_1^{\text{MC,conv}}, \dots, C_M^{\text{MC}} = n_{\text{pr}} C_M^{\text{MC,pr}} + n_{\text{conv}} C_M^{\text{MC,conv}}$$

Experimental counts

$$p(C_i) = p_{\text{poisson}}(C_i; \lambda(n_{\text{pr}}) = C_i^{\text{MC}}(n_{\text{pr}})) = \frac{\lambda(n_{\text{pr}})^{C_i} e^{-\lambda(n_{\text{pr}})}}{C_i!}$$

Maximize likelihood

$$\mathcal{L}(n_{\text{pr}}) = \prod_{i=1}^M p(C_i; n_{\text{pr}})$$

Easier: minimize negative log-likelihood

$$-\ln \mathcal{L} = -\sum_{i=1}^M C_i \ln \lambda(n_{\text{pr}}) - \lambda(n_{\text{pr}}) - \ln C_i!$$

With a constant conv norm: bin counts depend only on prompt norm = expectation value per bin

$$\Lambda = -2 \ln \frac{\mathcal{L}(n_{\text{pr}} = \hat{n}_{\text{pr}})}{\mathcal{L}(n_{\text{pr}}=0)} = -2 \sum_{i=1}^M C_i (\ln \lambda(\hat{n}_{\text{pr}}) - \ln \lambda(0)) - (\lambda(n_{\text{pr}}) - \lambda(0))$$

Test statistic for Wilks' theorem

Null hypothesis: no prompt
